

1. According to the article, "Rethinking the Race Between Education and Technology", what is the labor scarcity view according to a) David Autor, b) Carl Benedikt Frey and Michael Osborne, and c) Erik Brynjolfsson and Andrew McAfee? Describe in one-two sentences each.
 - a) David Autor - Rejects exaggerated reports of mass technological unemployment and argues that middle-skill jobs that mix foundational and vocational skills will survive despite automation.
 - b) Carl Benedikt Frey and Michael Osborne - Highlight the need to retrain workers for tasks requiring creative and social intellect, which computers cannot yet replicate but they also warn that 47% of US jobs are at risk of automation, especially low-skill jobs.
 - c) Erik Brynjolfsson and Andrew McAfee - Argue that robots and AI degrade common skills, leading to an obvious gap where only people with specialized training or higher education can succeed by using technology to create and capture value.
2. What is the educational response to labor scarcity?

Educational systems have to focus on STEM education, modernize curricula that promote digital skills, problem-solving, and creativity and encourage continuous learning with partnerships with employers to match training with changing business needs.

3. According to the article, "Rethinking the Race Between Education and Technology", the job scarcity view includes three different roles of workers. Identify each role and describe in one-two sentences each.

Developer roles, which are typically held by graduates of prestigious universities tasked with making strategic decisions, are high-skilled professions that require advanced competence, such as executives and researchers. In contrast, demonstrator roles encompass carrying out predetermined digital procedures in areas such as technical support or teaching; these individuals use standardized systems to apply existing knowledge and need to be able to interact with customers. Drone roles include low-discretion work where duties are tightly controlled by digital platforms, such as data input or scripted call center work. These jobs leave workers at risk of automation even if they have official qualifications.

4. What is the educational response to job scarcity?

Education systems need to adjust to the stratified labor market in order to overcome the employment shortage caused by automation. In order to prepare people for high-skilled responsibilities, institutions should give priority to elite, innovation-focused training for developer roles. Education programs for demonstrator positions should prioritize customer service abilities, consistent digital capabilities, and flexibility in implementing preset systems. Education for drone jobs must focus on fundamental digital skills, reading, and numeracy.

5. According to the article, "Rethinking the Race Between Education and Technology" the end of work view includes the idea that because information as a product is more freely available and less contingent upon physical production, the distinction between supply and demand, employers and employees and sellers and consumers will be blurred. What will people be called in this new world according to Jeremy Rifkin? Define (feel free to use the description provided in the article using quotation marks and including the author and page number).

Jeremy Rifkin calls individuals "prosumers", a combination of producers and consumers. In a cooperative economy, where information and digital tools allow for almost zero marginal cost production, consumers produce, distribute, and consume their own goods and services, dissolving the boundaries between ownership, labor, and consumption.

6. What is the educational response to end of work?

In the "end of work" scenario, education would promote continuous learning and full human development. The concept of "prosumers," who create, use, and distribute goods and services in a cooperative, almost cost-free market, would serve as the foundation for an updated educational system emphasizing civic engagement, creativity, critical thinking, and ethical reasoning. Instead of emphasizing job-specific training, educational systems would place more value on abilities that facilitate personal fulfillment and contribute to society, such as emotional intelligence, adaptability, and cooperative problem-solving. In order to enable people to succeed in a post-capitalist society, governments and institutions would need to separate education from the demands of the labor market and emphasize universal access to educational possibilities.

7. Which theory (labor scarcity, job scarcity or end of work) do you believe is the most plausible in describing how technology is transforming education now and how it could shape the future of work? Explain in one paragraph using your own educational experience.

In my opinion, the job scarcity theory is the most plausible in describing how technology is transforming education since it considers every level of the hierarchical labor market and offers a path to education for each. According to their skills, people can be trained to specialize in a developer, demonstrator, or drone job, highlighting the importance of every level of work to society. This hypothesis is also highly scalable, and it can still be plausible if the job market becomes even more stratified in the future. Since I'm an information technology student, I can understand how these three positions exist in my industry and call for various educational paths. As I'm in university and need advanced training to manage IT systems, I'm aiming for a developer position. This theory is most plausible to me as I can clearly see it in my professional and educational journey.
